UNIVERSITY, BIHAR**

# Gene library screening

2

Screening: Fishing the gene of interest from library

## Library screening methods

PCR based  
(Primer  
dependent)

Hybridization  
based  
(Probe  
dependent)

Immuno  
screening  
(Antibody  
dependent)

Screening of DNA

Screening of product

# PCR based screening of library

3

- ❖ It can be used to screen all libraries
- ❖ It has same versatility as of hybridization based methods
- ❖ Instead of spreading on solid plate, libraries are maintained in pool of diluting subsets
- ❖ Pools are maintained in multiwell plates
- ❖ Gene specific primers (homo/ heterologous/ degenerate) are used for in situ amplification
- ❖ Positive wells are identified

## PCR based screening of library contd.

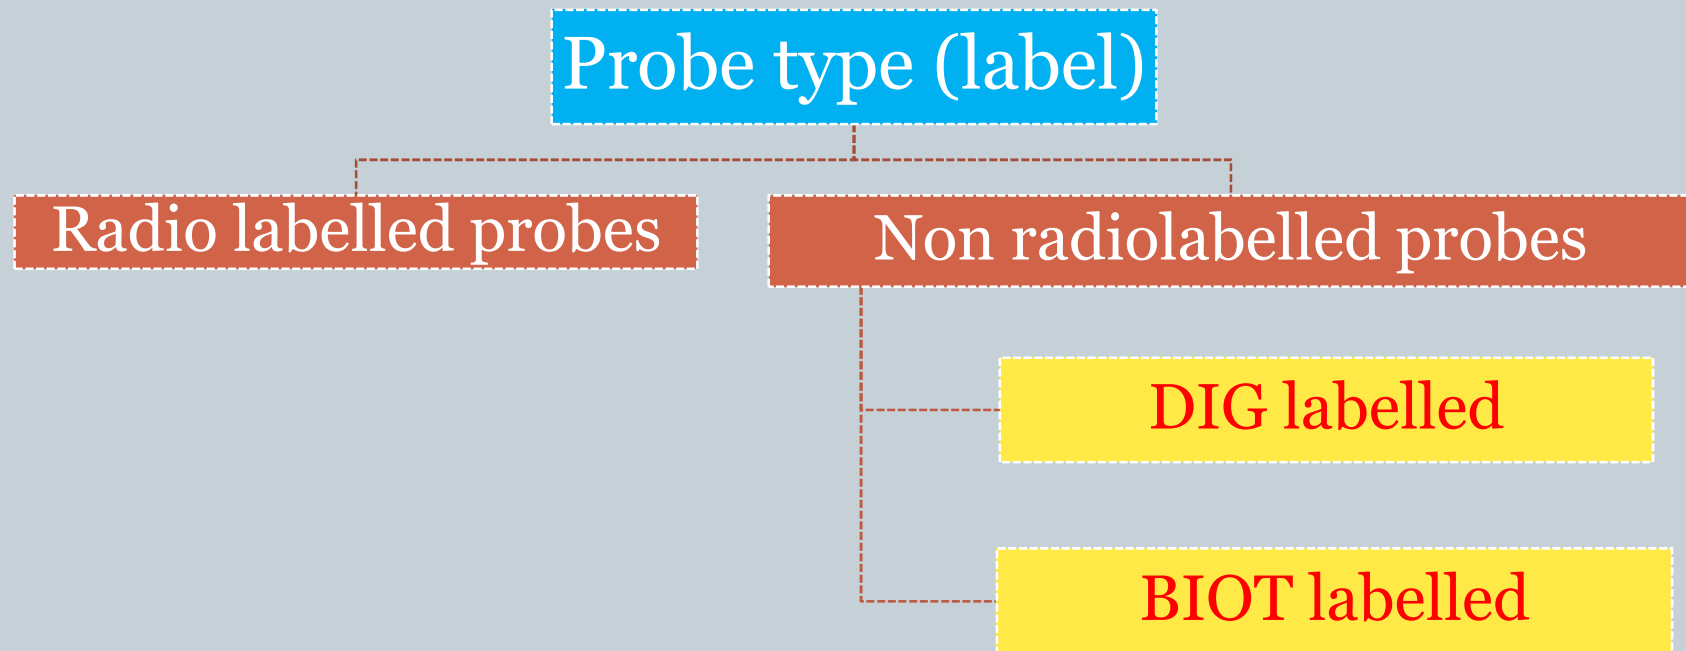

4

- ❖ Clones of positive wells are separately spread on solid plate
- ❖ Process continues till wells with homogeneous clones are identified

# Hybridization based screening

5

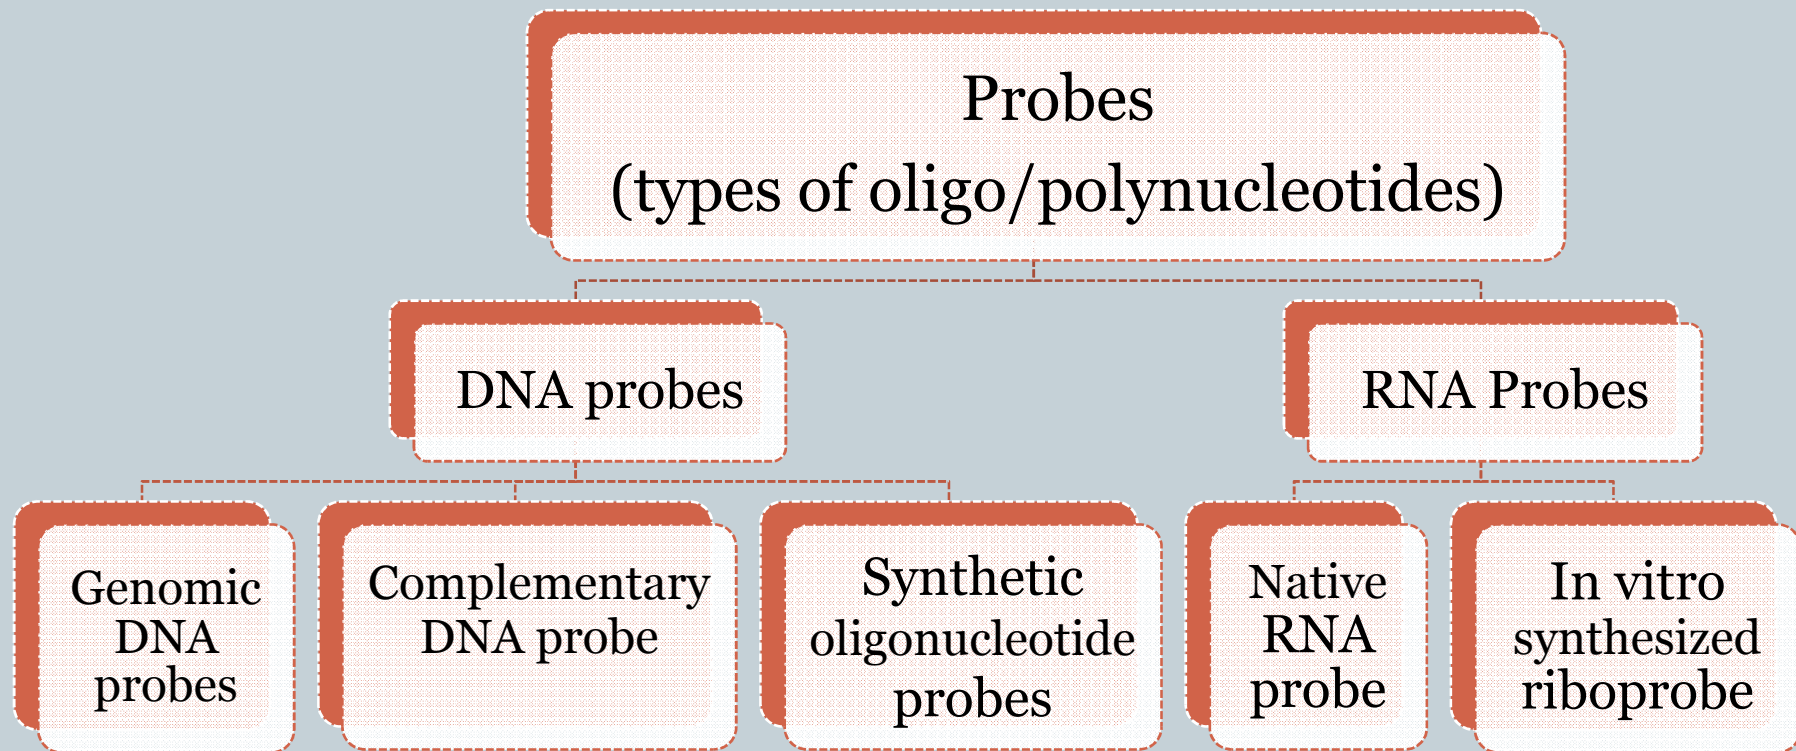

It is used for all kind of libraries and requires 'PROBE'  
PROBE-labelled oligo/ polynucleotide complementary to  
gene

For labeling  $P^{32}$ , DIG, BIOT labeled NTPs are used in different labeling methods

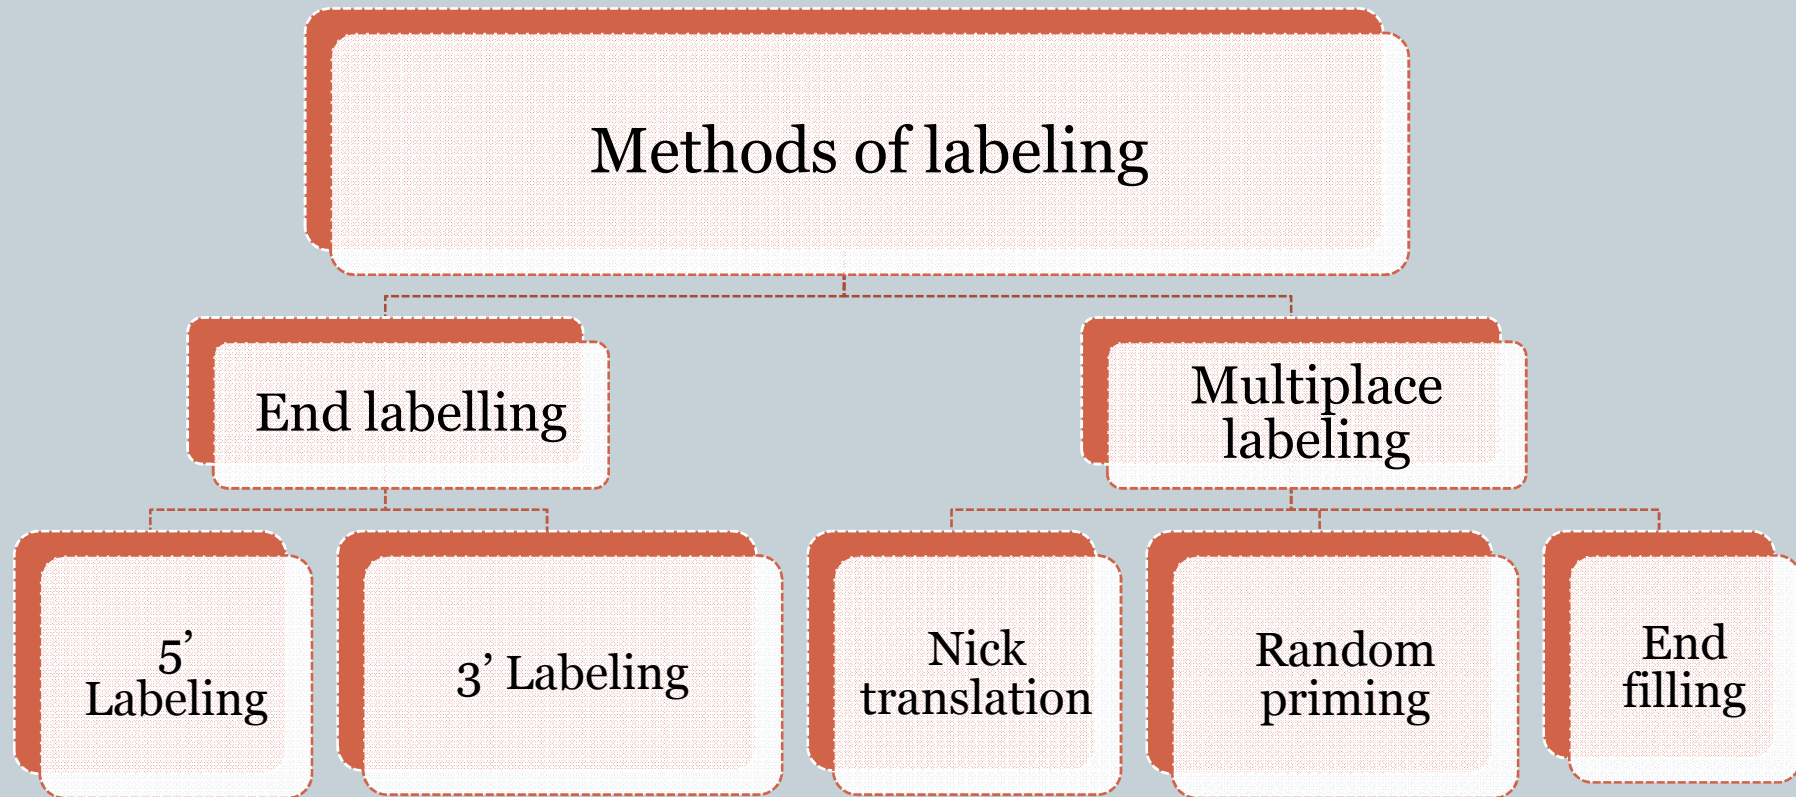

# Probe types

6

# Labeling methods

7

# End labeling of probes

8

dsDNA is labeled at the end only

Dephosphorylation using  
phosphatase (CIAP/BAP/SAP/AntP)

Rephosphorylation using  
Polynucleotide kinase and  $\gamma\text{P}^*\text{32 dATP}$   
(source of radioactive phosphate)

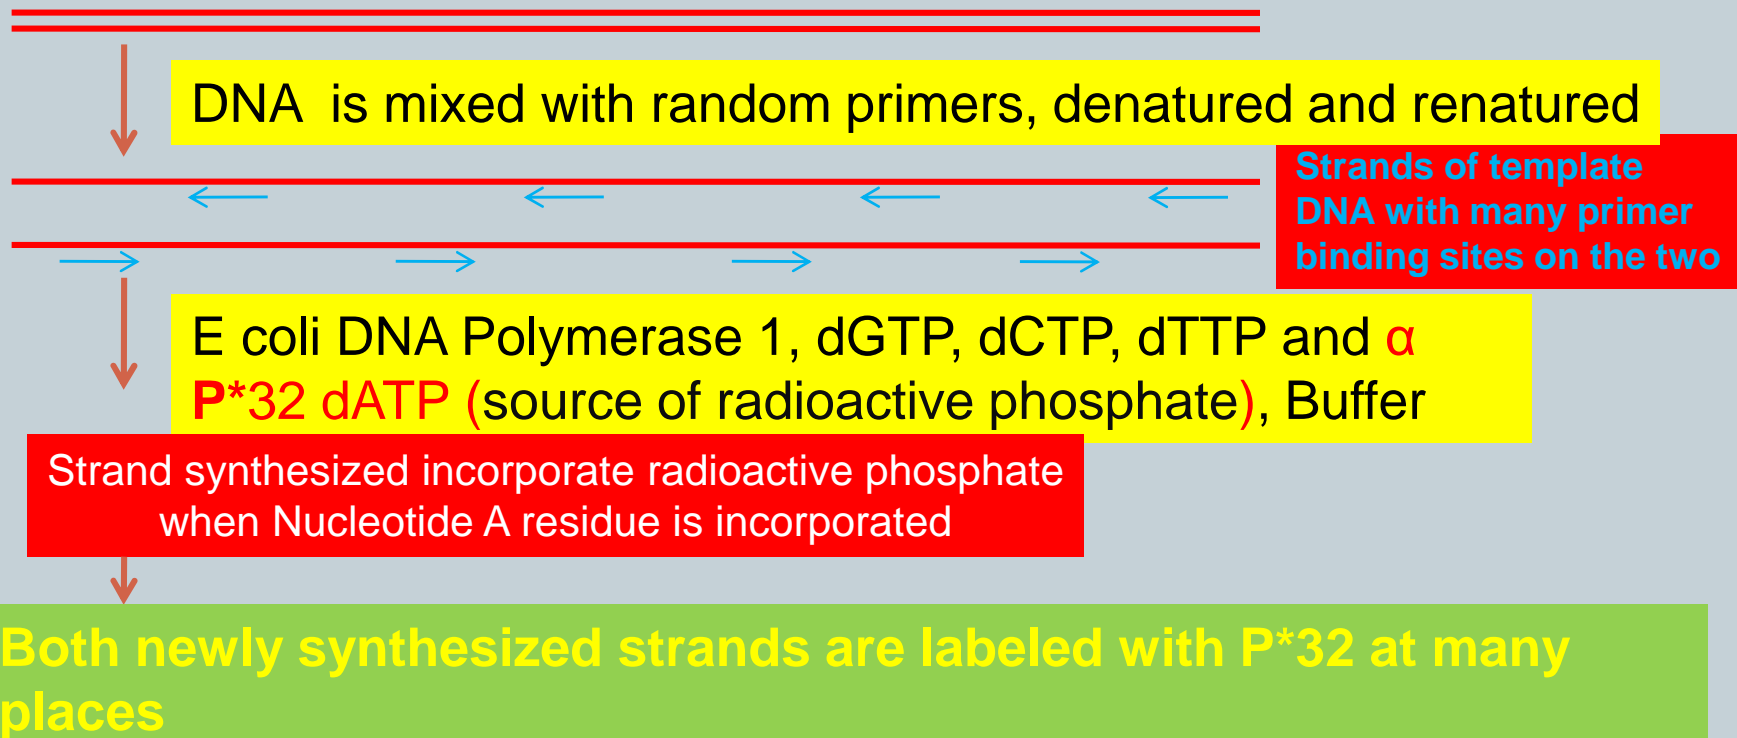

5' end labeled probe

# Random priming

9

Random primers are used to synthesize complementary strand in presence of radioactive nucleotide precursor and polymerase

# Nick Translation

10

**Nicks are created in DNA and in presence of polymerase nick is translated and radiolabeled nucleotide residues are incorporated**

↓  
DNase I (creates single stranded breaks called Nicks)

↓  
dGTP, dCTP, dTTP,  $\alpha$   $P^{*32}$  dATP (source of radioactive phosphate) and DNA polymerase I of E coli

↓  
5' to 3' exonuclease activity removes bases and 5' to 3' polymerase activity keep polymerizing simultaneously

Both strands of DNA are radiolabeled with  $p^{*32}$  labeled A residue at many places

# Hybridization based screening

11

Library spread  
on agar plate

Lift plaques on  
Nitrocellulose  
paper

Block membrane  
with prehybridization  
buffer

Lyse cells, denature protein and  
DNA, immobilize on membrane

Hybridize with  
labeled denatured  
probe

Stringency washing

Autoradiography

Spots on X-ray film

Spots showing positive signals are used to pick corresponding plaques/ clones from master plate (Library plate)

# Immunological screening

12

- ❖ It is used to screen library where cloned genes are expressed
- ❖ Works well with cDNA library
- ❖ Antibodies are raised against proteins coded by target genes
- ❖ Antibodies are used to identify proteins expressed from target gene when library is spread
- ❖ Secondary antibody conjugated to enzyme is used to identify specific primary antibody
- ❖ Reactions catalyzed by conjugated enzyme are used to locate specific clone

# Immunological screening

13

Library spread  
on agar plate

Lift plaques on  
Nitrocellulose  
paper

Block membrane  
with blocking agent  
like BSA/ Casein in  
PBS

Lyse cells, denature protein and  
DNA, immobilize on membrane

allowed to react with specific  
primary antibody

Washing allowed to react  
with secondary antibody  
enzyme conjugate

Washing and detection  
by reaction catalysis

**Spots of product  
formation on membrane**

**Spots showing positive signals are used to pick corresponding plaques/ clones from master plate (Library plate)**
